Abstract

Introduction: To describe a young Chinese male with muscle dysmorphia, a recently proposed variant of body dysmorphic disorder. Clinical Picture: A 24-year-old Chinese male with a morbid fear of weight and muscle loss with associated compulsive weight training, avoidance behaviour, forced eating, depressed mood and disturbed body image. Treatment: Antidepressants and cognitive-behavioural psychotherapy. Outcome: Preoccupation with muscularity was reduced. Conclusions: Muscle dysmorphia has been reported in Western populations, mostly among body builders and anabolic steroid abusers. To our knowledge, this is the first case report originating from a non-Western population. The patient illustrates the nosological difficulty of this recent entity. It is likely to be a culture-bound phenomena associated with a Western concept of an ideal body shape for males.

Key words: Body image, Body dysmorphic disorder, Cognitive therapy, Transcultural
